Q: Multiple namespaces in a single project I'm working on an application that needs to have multiple namespaces within the same project. The idea is that the application can consist of several different app domains and the application configuration can be read from the app domain. I'm looking for an architecture that allows me to have several different app domains within one project and I'm wondering if anyone knows of a suitable technology. To be specific, I'm thinking of something like this: I have a "Global" project and it defines an interface called IConfiguration. In my "Global" project I have several different classes (actually I know what I need here, but I want to discuss the architecture first) that implement this interface. These classes will be in a "Global" project. In my "Web" project I need to access the data stored in the configuration and I have a class that implements the IConfiguration interface. The question is, how do I create multiple instances of these classes without having to duplicate code? My current thoughts are to use dependency injection and have a factory that creates the objects based on some configuration settings. I also have to mention that I have multiple environments (DEV, TEST, PROD) and each one has its own configuration. I can think of a few problems with this approach: Is it a good design? How do I know that the object was created in the
